TWO DYKE EXERCISE

(1) Formation of the country rock

(2) Folding

Folding of the country rock into an antiform-synform pair with a wavelength of about 300 m, fold axis 45/230, axial plane 040/80NW, average limbs 007/55W and 050/V, interlimb angle 54°. The bisector, 031/71NW, has an apparent dip in the profile plane which is 13° less than that of the axial surface, indicating that the middle limb of the fold pair is thinner compared with the other limbs

(3) Intrusion of pegmatite (not folded and hence intruded after the folding)

Intrusion of a 10 m wide, parallel-sided, pegmatite dyke, 035/V

(4) Intrusion of dolerite (crosscuts the pegmatite and hence intruded after it)

Intrusion of a 6 m wide, parallel-sided, dolerite dyke, 085/V, with an opening direction normal to dyke margins

(5) Faulting (fault offsets dolerite and hence post-dates it)

We'll fill in the details of the fault movement in Class 3

(6) Uplift and erosion to the present topography
