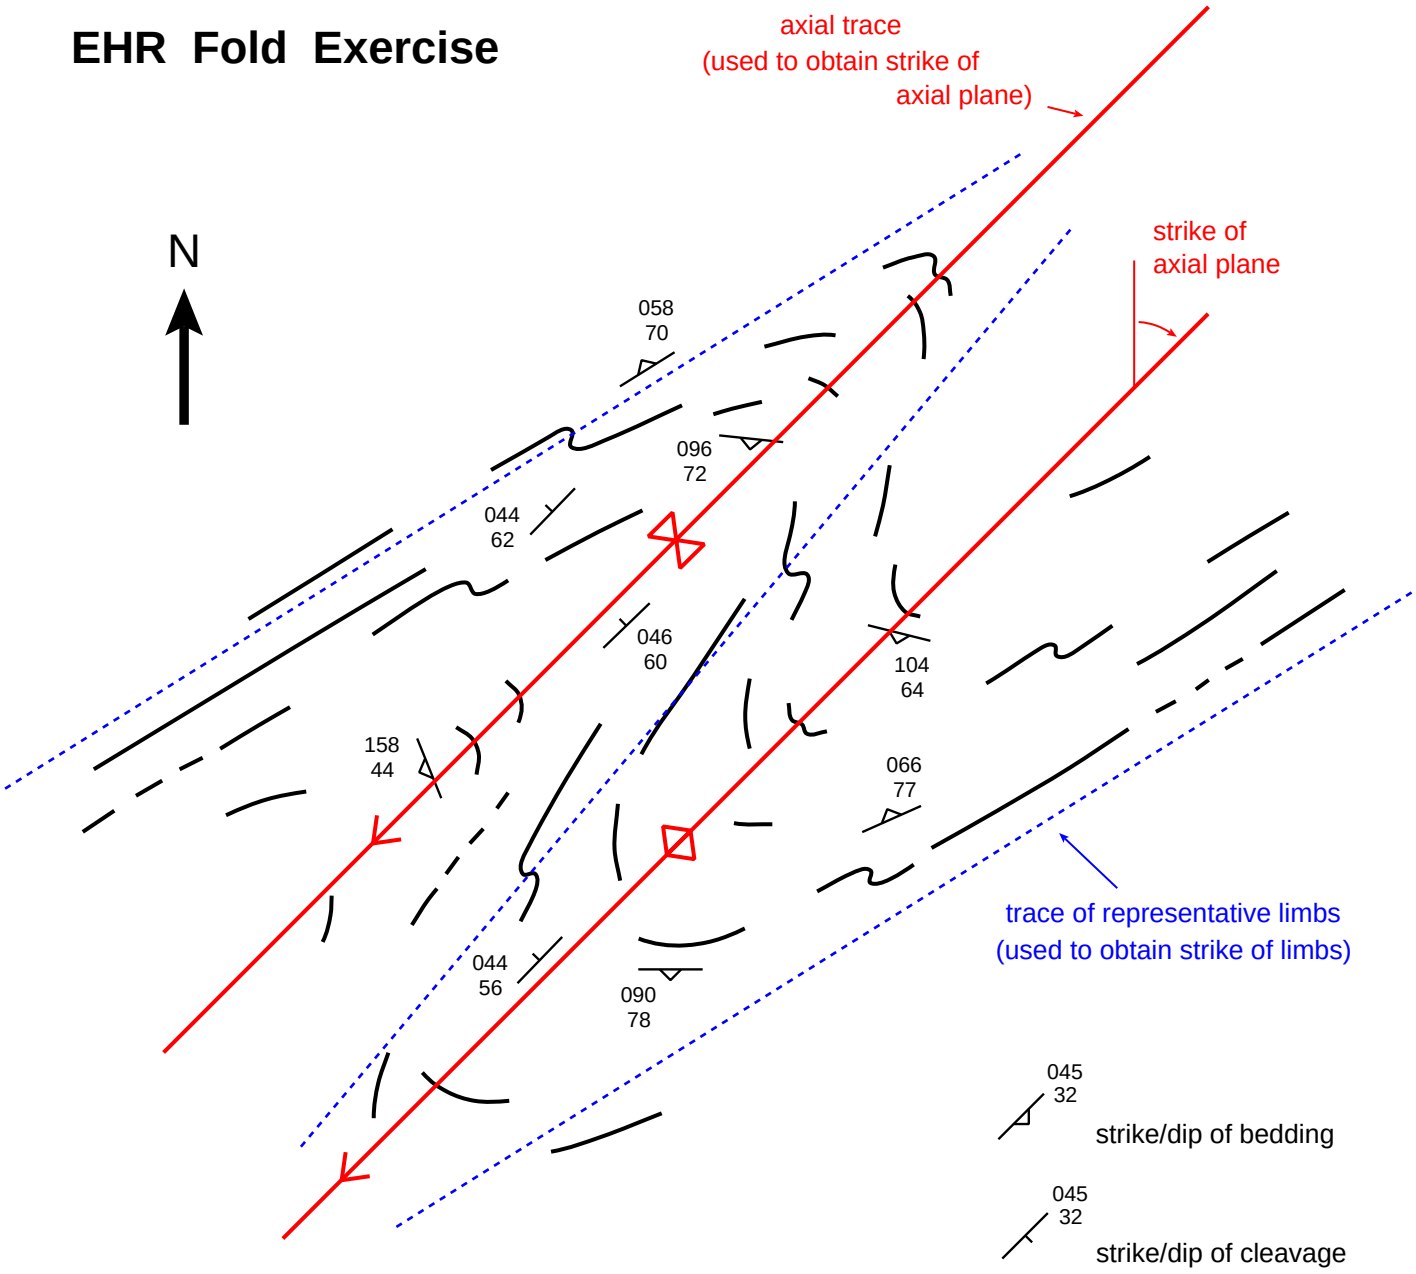
EHR Fold Exercise



Mark and label the axial traces of the folds on the map

By plotting a stereogram

- Find the orientation of the fold axis
- Find the orientation of the axial plane
- State representative orientations of the limbs
- What is the interlimb angle?

The asymmetry of the minor folds changes systematically across the major fold traces and the boudinage is concentrated in the major fold limbs. This is consistent with these structures being congruous with the major structure, and hence the minor fold axes and boudin necks should be parallel to the major fold axis (42/257)

Answer the following:

- Is the cleavage axial planar? YES
- What is the probable orientation of the minor fold axes and boudin necks?

Draw a simplified profile plane section, stating which way you are looking along the fold axis (up or down plunge)
